Under the Volcano: Mount Mayon and Co-volcanic Societies in the Philippines

Greg Bankoff

Abstract

Rich volcanic soils have long attracted human settlements which have traded the risk of eruption against the benefits of higher agricultural yields. Yet little research has been done on how societies have normalized the risks and adapted to living in proximity to volcanoes, or how those modifications, in turn, might have influenced the effects of eruptions and the consequent hazards. That is how people have co-evolved with volcanoes, to create “co-volcanic societies”. By looking closely at the Philippines and focusing on one region of southern Luzon around Mount Mayon, this article addresses the question of how people and volcano have “co-adapted” to living in proximity to one another over time. It also suggests that to make societies more resilient to volcanic hazards, a better understanding of this relationship is required not only to improve current disaster risk reduction (DRR) policies but even to inform everyday urban planning and civil engineering decisions.

Keywords: co-volcanic societies, volcanoes, Mount Mayon, Philippines

Volcanoes are one of the most powerful forces of nature. Single eruptions have devastated cities, modified landscapes and even altered climates. Historical case studies demonstrate the devastating impact of eruptions. The eruption of Tambora (Indonesia) in 1815 perhaps changed the course of European history (Battle of Waterloo) and triggered the Year without a Summer. In 1902, pyroclastic density currents killed over 28,000 people and destroyed the city of St. Pierre, the “Paris of the Caribbean” during the eruption of Mt. Pelée (Martinique). The lahars from Mt. Pinatubo (Philippines) in 1991, the second largest terrestrial eruption of the 20th century, altered the topography of Central Luzon. Since 1900, nearly five million people have been affected by volcanic events and over 91,000 people have died directly from ash asphyxiation, thermal injuries from pyroclastic density currents, and trauma. Moreover, these figures are unlikely to reflect the true extent of casualties given the inconsistent reporting of such events, particularly with respect to the number of injured and affected.

Approximately nine per cent of the global population or more than 500 million people now live within the potential exposure range of the 550-odd active volcanoes that have erupted within the last 10,000 years. As populations continue to grow, an increasing number of

1 Weather conditions on the battlefield of Waterloo, particularly the muddy terrain caused by heavy rains attributed to the volcanic ash in the atmosphere from the massive eruption of Tambora a few months earlier, has been blamed for delaying Napoleon's attack on Wellington's position and for hampering his troops' frontal assault uphill. Dennis Wheeler and Gaston Demarée, ‘The Weather of the Waterloo Campaign 16 to 18 June 1815: Did It Change the Course of History?’ *Weather* 60 (6) (2005): 159-164.

urban centres located near to active volcanoes will place more people, property and infrastructure at risk than ever before.

Despite the self-evident dangers of living too close to a volcano, fertile soils have long attracted human settlements whose residents have traded the risk of an eruption against the advantage of higher agricultural yields. As yet, however, little research has been done on the manner in which societies have normalised the risks and adapted to living in close proximity to volcanoes: how communities have co-evolved with volcanoes, balancing the benefits of rich soils and good harvests against the threat of sudden death and destruction, and, by their activities, modifying the landscape and so affecting the course of eruptions, to create what can be called “co-volcanic societies”. Through history, people have learnt to live with volcanoes in different ways. Some people have “moved” their city to safer locations. In Costa Rica, the capital was transferred from Cartago (founded 1563) to San José in 1823 because of the constant destruction wrought by Irazú Volcano. Other people have sought to appease the volcano by deifying it. Hawaiian Islanders and the Maori of Aotearoa/New Zealand elaborated religious practices around their daily activities as a form of psychological accommodation to the danger of living with volcanoes. Still others have tried to structurally modify the landscape through feats of engineering; Romans in the 5th century BCE constructed a tunnel to regulate the level of the volcanic Lake Albano in Italy.4

By looking closely at the Philippines, ranked as the second most dangerous country in the world to live in, and focusing on one region of southern Luzon around Mount Mayon, the most active volcano in the archipelago, this article addresses the question of how people have co-adapted to living in close proximity to a volcano over time.5 It proposes two related propositions: that communities and cultures are shaped by living with the constant threat of volcanic eruptions, and that the course (not the type or timing) of such eruptions, particularly the flow of lava and lahars are altered by human modifications to the surrounding landscape. It also suggests that to make society more resilient to volcanic hazards, a better understanding of this relationship is required not only to improve current disaster risk reduction (DRR) policies but even to inform everyday urban planning and civil engineering decisions. The Philippines provide just such a landscape of risk from which to explore the concept of “co-volcanic societies”. It has 23 active volcanoes, has experienced at least one killer eruption claiming more than a thousand lives each century for the last 200 years (Mayon Volcano in 1814 and Taal Volcano in 1911), and, in Mount Pinatubo (1991), has been subjected to the

---

largest eruption ever to have affected a densely populated area in the archipelago. Just as Popocatpepetl and Iztaccihuatl cast their shadows over the protagonists’ lives in Malcolm Lowry’s masterful novel (1947) of the same name, so have the communities around Mount Mayon, over time, learnt to live “under the volcano”.

Co-volcanic societies

Scholars have long been intrigued by the idea that people who are frequently exposed to hazard adapt their behaviour to accommodate risk and that these patterns can become embedded to some extent in cultures over time. Harry Moore is credited with first coining the term “disaster subculture” to describe “those adjustments, actual and potential, social, psychological and physical, which are used by residents of such areas in their efforts to cope with disasters which have struck or which tradition indicates may strike in the future”. Moore was writing about how people who lived in coastal communities acted as Hurricane Carla hit Texas in September 1961 and explained their behaviour as pertaining to a “hurricane subculture”. Moore never went on to fully formulate his ideas; this was left to a research paper by Dennis Wenger and Jack Weller written nearly a decade later. Based on research carried out in a number of communities across the United States regularly affected by flooding and hurricanes, they sought to uncover the existence of disaster sub-cultures through indices that showed “the perpetuation of successful patterns of adaptation to the disaster context through socialization”. Rather than viewing disaster subcultures as special arrangements apart from the general culture of the community that are resorted to in times of need, more in the way Moore argued, Wenger and Weller regard the subcultural traits that evolved out of the experience of disasters as fully integrated into the dominant non-disaster culture, able to be passed down from one generation to the next, and as transmissible to new community members. They went on to identify three factors that appear to be crucial to the emergence of a disaster subculture within a community: that a hazard has to be repetitive, of such a nature as to allow a period of forewarning, and that its consequences inflict significant damage to human and material resources.

As the factors identified by Wenger and Weller indicate, these scholars were particularly concerned with recurring hazards such as hurricanes/typhoons and floods that promoted cultural adaptations in affected communities through the regularity of their occurrence. Earthquakes, too, if they are along tectonic faults also satisfy these criteria: they occur at frequent if irregular intervals, people living in seismically active areas know they are at risk, and the consequences inflict significant losses in terms of mortality and material damage. The historical frequency of earthquakes in Japan, for instance, has shaped the material and

8 Ibid., pp. 2-5, 9.
symbolic culture of that society to such an extent that Greg Clancey dubbed it an “earthquake nation”.

With reference to the 1999 Kocaeli (Izmit) Earthquake in western Turkey, Jacqueline Homan and Warren Eastward recognise a “seismic culture” comprised of very specific adaptations to the hazard of earthquakes. They define seismic cultures as those having: “The knowledge (both pragmatic and theoretical) that has built up in a community exposed to seismic risks through time”.

This knowledge may be expressed in a society’s architectural forms and building techniques as in the case of Japan and Turkey or it may be embedded in a community’s local knowledge and oral traditions. In non-literate societies or where literacy is the preserve of the elite, important evidence on the history of past disasters and communities’ successful coping practices may be embedded in the myths, legends and rituals passed down through the generations. While these narratives may constitute a record of a culture’s memory of past geological events such as major floods, earthquakes and volcanic eruptions, the information is often expressed in metaphorical language to ensure its faithful recollection and dissemination and so requires careful decoding of its symbolism. It is also often a mechanism for attributing meaning and responsibility to some external source, whether it be god or hero, for an event beyond the human power to comprehend or control, and so provides a culturally acceptable explanation to reduce collective trauma.

Whether cultural adaptation takes place, however, when the hazard occurs less frequently such as in the case of a volcano is a more difficult question to answer. While a volcano’s dominance of a surrounding landscape is a constant visible reminder to those who live around its base of the potential risk, the infrequency with which they may erupt, with some lying dormant for centuries, usually creates a sense of complacency among the surrounding population who forget the threat to which they are exposed. For instance, the explosive eruption of Mount Pinatubo in 1991 occurred after some 400-500 years of inactivity. These cataclysmic eruptions, however, often provide little opportunity for cultural learning and frequently lead to the abandonment of the immediate area and the relocation of the population to a new site. Other volcanoes, however, erupt with much greater frequency: Kilauea Volcano on Hawaii is the world’s most active volcano, followed by Etna in Italy, and Piton de la Fournaise on La Réunion Island. As a consequence, local populations there have had to adapt to living with the likelihood that an eruption might occur at any time and take steps to mitigate the risk. Over time, these measures become embedded in local cultures. In his study of villagers’ adaptation to living on the slopes of Mount Merapi, the most active volcano in

Indonesia, for instance, Michael Dove noted the way the local agricultural economy not only “naturalised” but actually utilised volcanic perturbations to the extent that they could be said to have created “a culture of volcanic hazard”. Moreover, he argues that even the concept of natural hazards likely co-evolved with the hazards themselves so that natural perturbations and their cultural construction have historically developed in tandem. The more recent focus on interdisciplinary research has also led to what Katherine Donovan calls the emergence of “social volcanology” as a means of reducing volcanic risk by an examination of local societies.

The necessity for such research in the Philippines is pressing given that more than 80 per cent of the total national population live in close proximity to an active volcano, one of the highest concentrations of people in the world. City dwellers, however, all too soon forget the customary lore and local practices that helped ensure the safety of their rural forebears and so put themselves and their families at greater risk when eruptions occur. An archipelago located off Indochina in the Western Pacific, the land area of the Philippines totals little more than 300,000 km² spread over more than 7000 islands. The archipelago lies on the Pacific Rim of Fire, a 48,000 km long horseshoe rimming the Pacific Ocean from Indonesia to Chile where over 75 per cent of all volcanoes in the world are located and where nearly 90 per cent of the world’s earthquakes happen. Wedged between the much larger Pacific and Eurasian tectonic plates, the continuous collision and subduction of the small Philippine Sea Plate make the archipelago an area of extreme geophysical activity. Disasters, therefore, are simply a fact of life for most Filipinos. A socially and economically vulnerable population of more than 100 million where over one in four families lives below the poverty line combines with one of the world’s most hazardous landmasses to make disasters there a “frequent life experience”.

**Mayon Volcano**

Volcanic activity has been frequent and destructive in the Philippines. Currently there are 23 volcanoes in the archipelago listed by the Philippine Institute of Volcanology and Seismology

18 S.K. Brown, M.R. Auker and R.S.J. Sparks, ‘Populations around Holocene Volcanoes and Development of a Population Exposure Index’ in Susan C. Loughlin, Steve Sparks, Sarah K. Brown, Susanna F. Jenkins and Charlotte Vye-Brown (eds), *Global Volcanic Hazards and Risk* (Cambridge: Cambridge University Press, 2015), p. 224. The Philippines (82 per cent), Indonesia (84 per cent) and Japan (89 per cent) are the countries with the greatest number of people living in close proximity to volcanoes though Guatemala and Iceland, with much smaller total populations, have over 90 per cent of their population living in such areas.
(PHIVOLCS) as active. Active volcanoes are those with either a documented eruption within historical times (i.e. the last 600 years) or where an eruption can be shown to have taken place within the last 10,000 years based on analyses of datable materials. The two most active volcanoes in the country are Taal Volcano and Mayon Volcano. Taal is located in central Luzon less than 50 km from the densely populated capital city of Manila and has erupted over 30 times since 1572, most notably in 1911 when it killed 1300 people. Its eruptions are sometimes accompanied by tsunami-like waves as the water in the caldera from which the volcano rises often inundates the surrounding countryside, flooding towns and settlements. The archipelago’s most active volcano, however, is Mount Mayon in Albay, the second most southerly province on the main island of Luzon. Mayon is a stratovolcano with a perfectly shaped cone and a basal circumference of 63 km that rises to an elevation of over 2600m. Known locally in the Bikol language as Daragang Magayón (The Beautiful Lady), the volcano has erupted over 50 times since February 1616 when a passing Dutch explorer, Joris van Spilbergen, recorded an eruption in his ship’s log and described the mountain as “constantly burning” and being “full of sulphur and such-like things”.

---

However, there are few recorded accounts of eruptions prior to 23 October 1766 when “a horrendous explosion” caused a river of molten lava “fathoms-wide” to flow down the sides of the volcano and devastate the town of Malinao and the surrounding villages, killing many hundreds of people.24 Undoubtedly, there were many other eruptions before the 19th century that have yet to be documented; the 50 or so subsequent events suggest that the volcano erupted frequently and there is little reason to suppose that activity in the 17th and 18th centuries was any different. After the eruption of Mayon in 1800, however, there is a detailed historical record of volcanic activity. Most of these eruptions have been fairly minor with a Volcanic Explosivity Index (VEI) of two or less. Despite this low VEI, the volcano was often in a continuous eruptive state for decades at a time. For example, in the 1850s, there were two minor eruptions of ash in 1851, a major eruption on 13 July 1853 that killed 33 people and destroyed many houses, another on 22 March 1855, and yet another in 1857 that produced so much ash that it reportedly killed all the bees in the region. The volcano was active “almost without interruption” in 1858, while a resplendent glowing cone lit up the night sky on most clear nights between 1859 and 1860.25

On still other occasions, however, the volcano vented its full fury. The deadliest recorded eruption took place on 1 February 1814. An immense column of smoke and ash rose suddenly from the summit and spread rapidly, completely darkening the sky while a torrent of fire, lava and incandescent stones flowed down the southern flanks of the volcano “devastating, burning and consuming everything in its path”.26 According to contemporary descriptions, the death toll reached 1200 and three towns were completely devastated and two others partially destroyed. Another major eruption began on 23 June 1897 and lasted for four days. Huge columns of dust-laden vapour escaped from the crater while great quantities of molten lava and incandescent rocks poured down its slopes. Volcanic bombs and lapilli (rock fragments) were thrown high into the sky as flashes of electric lightning zigzagged about the cone. Many settlements at the foot of the volcano were destroyed completely and the town centre of Libog (present-day Santo Domingo) was only saved by what was described as a “ridge” that retained the flow of lava within the preexisting channel of the Basud River. An eyewitness account suggests that an accompanying pyroclastic surge overwhelmed some women as they dried their hair out the windows, leaving their bodies to be discovered in this position.27 Ash reportedly fell over an 80 km radius while the volcano’s subterranean rumblings were heard as far afield as Manila. Reliable estimates place the number of dead at

27 Interview with 86-year-old informant, Santo Domingo, 20 January 2018. The interviewee was evidently not alive in 1897 but graphically remembers the stories told her about the eruption by her grandmother in the 1930s.
approximately 200 people.\(^{28}\) Both these eruptions were larger with a VEI of at least four.\(^{29}\) Eruptions in the 20\(^{th}\) century have been smaller, only reaching VEI 3 (1984) but have still been destructive.\(^{30}\) There were few or no casualties from the eruption that began on 10 September 1984 but PHIVOLCS considered it prudent to order an evacuation of more than 73,000 people from the danger zone. In the more recent eruption of 3 February 1993, a pyroclastic density current sped downhill at approximating 300 km an hour catching many farmers in their fields and killing 77 people as well as causing losses to farmland, crops, fisheries and wildlife.\(^{31}\)

People living within close proximity to the volcano are also at risk from lahars even when an eruption is not in progress. The loose-lying debris from the continuous volcanic activity that covers the mountain’s slopes pose their own dangers and can be suddenly unleashed by the torrential rains of passing tropical storms or typhoons.\(^{32}\) This material can flow with considerable volume; boulders are usually transported in debris flows several metres deep though much shallower depths are able to upset the equilibrium of even relatively large rocks several metres in diameter. Once set in motion, however, there is nothing to stop the descent of these boulders until they reach the low depressions at the base of the mountain or roll into the sea at the Gulf of Albay.

There are, at least, three documented accounts when heavy rainfall caused major loss of life. The first great disaster of this kind happened in October 1776 when thousands of people were reported to have died although there are no precise mortality figures.\(^{33}\) The second occasion is often erroneously attributed to an actual eruption of Mayon Volcano on 31 October 1875. A close reading of the accounts, however, suggests instead that the probable cause of the 1500 deaths were the lahars unleashed by the rainfall of a passing typhoon. Quite apart from the number of casualties, the mudflows devastated an area of farmland greater than in many previous eruptions.\(^{34}\) The result on both these occasions was one of desolation, leaving

\(^{33}\) Le Gentil, *A Voyage to the Indian Seas*, pp. 9-10. There is some confusion over whether this event took place in 1766 or 1776 and whether the eruption and the lahar were separate or related events. The authenticity of Le Gentil’s accounts has been called into question on more than one occasion and Faustino clearly identifies the event as occurring in 1766 though it is not clear on what grounds he makes this assumption. Faustino, ‘Mayon Volcano’, 11.

\(^{34}\) Enrique Abella y Casariego, ‘El Mayon, or the volcano of Albay (Philippines) 1 April 1882’, p.3, manuscript held by the Philippine Institute of Volcanology and Seismology (hereafter PHIVOLCS) Library, PL M001.
behind “a mere expanse of bowlders [sic] and sand with pieces of wood and branches of twigs to mark the place where once was a field, a garden, or a thriving community”. Lahars remained a constant menace, threatening sudden death to communities throughout the 20th century. Leopoldo Faustino, assistant chief of the Division of Geology and Mines, warned of just such another impending tragedy in a letter to the provincial governor of Albay, Mariano Locsin, shortly after the eruption in June 1928. After visiting the volcano, he wrote that there was a danger “at the present time from the fragmental materials lying unstable on the slopes of the volcano, which with the coming rains may sweep down the mountain sides in torrential flood”, and urged that the inhabitants of settlements in their path be warned of the danger. In November 2006, Typhoon Reming (international codename Durian) did just that as it swept through the Bikol provinces dumping over 460 mm of rain on the sides of the volcano and causing massive lahars that officially killed 754 people but unofficially perhaps as many as 1200, affected 1.54 million more, and devastated the surrounding rice fields and coconut plantations.

To the inhabitants of the province of Albay, volcanic eruptions are not infrequent events that occur at intervals of two or three centuries. Instead, eruptions are just another thing that locals have had to learn to live with and have come to expect as necessarily a part of the daily routine of life “under the volcano”. At the same time, the constant and growing human activity around the base of the volcano has reshaped the environment over the centuries to such an extent that it affects the manner in which eruptions unfold, influencing the direction and extent of lava flows and lahars. This cultural adaptation on the one hand, and this physical restructuring of the landscape on the other hand, has led to the emergence of a co-volcanic society around Mayon Volcano.

Volcano’s effects on society

As only to be expected from so much volcanic activity and plentiful rainfall throughout the year, the plains of Albay are very green and fertile. In fact, the four provinces of the Bicol region were historically considered among “the richest on Luzon” due to their agricultural wealth. From Mayon’s summit, according to Faustino who climbed its slopes on his visit to the volcano in 1929: “Land and sea, fields and forests, villages and towns with their churches and government buildings stretch out in diminutive form as far as the eye can see”. Volcanic soils or andisols cover less than one percent of the world’s surface yet they support ten per cent of the world’s population including some of the highest human population densities. The fertility of volcanic soil lies partly in its non-crystalline mineral content that reacts favourably with growing organic matter, and partly in its powdery consistency that

---

35 Faustino, ‘Mayon Volcano’, 11.
36 Ibid., 3.
retains a high amount of water beneficial to plant growth. This soil is the result of accumulated volcanic ash that follows eruptions and forms a nutrient-rich layer that facilitates plant growth and agriculture as long as the depth does not exceed 15cm. If the ash is too deep, however, the cinder-mulch leads to an imbalance of minerals and adversely affects the health of plants and animals.

Soil apart, the regularity of eruptions also has a dramatic impact on the surrounding vegetation, affecting the distribution and type of plants especially on the volcano’s flanks. The entire summit of Mayon was reportedly “entirely barren” when Fedor Jagor, the German naturalist and explorer, climbed the volcano in 1859-1860. Yet by 1929, Mayon’s northern and western slopes were swathed in vegetation almost to its tip, with trees up to 50cm in diameter heavily covered with epiphytes, suggesting that no heavy flows of lava or lahars had taken this direction for many years. At the same time, however, the southern and eastern sides of the volcano were practically barren composed of nothing more than sand and boulders set to slide at every opportunity. Only the lower slopes were covered by cogan and other grasses, and an occasional patch of raspberries. In the surrounding plains, on the other hand, the andisols, the rich volcanic mulch, was very conducive to subsistence and, later in the nineteenth century, commercial agriculture. In particular, Albay had a thriving trade in abacá (Musa textilis) or Manila hemp used extensively for rigging in sailing ships. Along with coconut trees (Cocos nucifera), much of the region’s wealth was invested in these two exports. Though generally beneficial to agriculture, in the short term, eruptions could have serious consequences. Showers of dust and ash reach distances of over 40kms, turning the leaves of abacá plants brown and wilting the fronds of coconut trees, often killing them. The wind direction is crucial in determining the extent of the devastation, even blasting the windward side of tree trunks and bamboo, while leaving the lee side green and apparently unharmed. However, this damage is usually only of a temporary nature.

While the volcano’s effect on the region’s soils and vegetation may have been the most apparent impact, attracting population to cultivate the land under its shadow, Mayon exerted an even more profound influence on the rhythm of daily life and the spatial patterns of human settlements. Living in close proximity to the volcano required that people be ready to

evacuate at a moment’s notice and to be constantly reading the signs forewarning of an impending eruption. Warnings such as micro-earthquakes, volcanic tremors, subterranean rumblings, ground deformation and signs of fire in the cone at night often preceded an eruption. The town of Libog, for instance, was “more or less deserted” prior to the eruption of 27 June 1928 as its inhabitants had heeded the signs and had evacuated. Sometimes, these warnings began weeks beforehand, spreading terror amongst local residents and persuading entire communities to flee and leave whole towns deserted “for more than a month” at a time. At least 5000 “panic-stricken” people reportedly abandoned their homes near the base of the volcano in 1928 and moved to places of safety such as the refugee camps set up under the supervision of the Red Cross. Still this was preferable to the danger that otherwise came upon people caught unawares. Pyroclastic surges of swiftly flowing, dense clouds of hot gases, ash, and lava fragments known locally as lawi lawi might sweep silently down the flanks of the volcano and suddenly overwhelm the unsuspecting inhabitants in the lands below. Such was the fate that overcame Barrio Bigaa, an outlying settlement of Legazpi (Albay) in June 1928, as “men, women, and children seeking safety, ran pell-mell, carrying what little belongings they could gather together on the spur of the moment, driving before them in all directions domestic animals filling the air with shrieks and howls – a veritable pandemonium”. Much of the surrounding land is vulnerable to this peril: a pyroclastic density current on 21 April 1968 reached seven kilometres from the summit and descended to an elevation of 200m.

While the temporary need to evacuate existing settlements was seemingly a constant feature of life around the volcano, the site of the towns themselves were often determined by the particular characteristics of Mayon’s eruptive phases. While wind direction was always an important determinant in deciding which communities were more at risk than others, successive eruptions did change the contours of the cone’s rim and therefore affected the direction lava and lahars might take. Seasonal wind directions in the Philippines are dominated alternately by the trade winds and the monsoons. Between September/October and May/June, the prevailing wind is from the east (Amihan) and characterised by moderate temperatures with little or no rainfall, but for the rest of the year, the prevailing wind is from the west (Habagat) and characterised by hot and humid weather with frequent heavy rainfall. The exact fallout area of any ash cloud, therefore, reflected when the eruption occurred with some settlements being more at risk than others at certain times of the year. If seasonal wind directions have not fluctuated dramatically over recent centuries, the likely direction of lava flows and lahars have changed dramatically on several occasions. Towns considered relatively safe when settled might later prove to be in the direct path of oncoming lava and lahars as the height of the cone’s sides varied or the channels that ran down the flanks of the

---

49 Faustino, ‘Mayon Volcano’, 25.
50 Singg, ‘The Beauty of Mayon’, 70.
volcano shifted. Father José Coronas noted just such developments in his treatise on the 1897 eruption of Mayon, observing how the path the lava took had changed over the years. Beginning with a description of the 1814 eruption, the lava had destroyed the towns of Cagsawa, Camalig and Budiao, all situated on the southern side of the volcano. Similarly, the flow of lava had all been to the south and southeast in the 1871, 1881, 1885, 1886 and 1887 eruptions. During this latter eruption, however, the volcano’s cone had been modified and, in the eruption of 1890, the lava flowed down the eastern flank of Mayon in the direction of the town of Libog that had been previously largely spared such dangers. 54

The shifting nature of this threat persuaded entire communities to relocate on occasion. The inhabitants of the doomed town of Cagsawa had petitioned the provincial governor to transfer their town to Daraga in 1771 due to the dangers posed by frequent lahars. 55 Alas, the relocation was never realised before the deadly eruption of 1 February 1814. This is the first event for which there are detailed records of the course and aftermath of the eruption. Accounts give a harrowing description of its progress and of the deaths of 1200 residents in nearby settlements. 56 In all, maybe some 30,000 people were directly affected. However, it is the ensuing debate over the relocation of certain towns that is most illuminating. Three towns were quite literally burnt to the ground, Cagsawa, Camalig and Budiao, while two others, Guinobatan and the provincial capital, Albay, were badly damaged though the churches and municipal buildings of both places survived. A new vent had reportedly opened on the volcano’s flanks and had proven particularly fatal to the town of Budiao that had literally been “erased” from the earth with as many as 200 people alone perishing in the church. 57

The question of relocation was picked up again with renewed urgency in the aftermath of the disaster. Already by 16 February, the Alaclée-mayor, the provincial governor of Camerines, wrote to the governor-general in Manila suggesting that not only the five ruined towns of the Iraya be relocated but that the remaining three also be removed to a safer area. 58 In fact, many local townspeople had already taken matters into their own hands and had moved to new locations. The inhabitants of Camalig, for instance, had settled more than a league (5.5 kilometres) away from the volcano but near enough to their old site that the remaining residents could still use the existing irrigation system to water their new fields. With the support of the local parish priest, they petitioned the provincial governor to officially recognise their move and asked, in addition, for relief from tribute and taxation for the next

54 Coronas, The Eruption of Mayon Volcano, p. 18.
56 This number may have been inflated by Fr. Aragoneses as it suggests that nearly 20 per cent of the local population died in the eruption, a somewhat exceptional figure. Francisco Aragoneses, Suceso Espantoso Acaecido en la Erupcion del Volcan de Alba en la Isla de Luzon, una de las Llamadas Filipinas (Madrid: Imprenta de Nuñez, 1815). Aragoneses’s account was primarily written to solicit charity for the affected towns in Spain and a higher death toll may have seemed justified in the circumstances. Interview with local historian, Camalig, 17 January 2018.
57 ‘La Erupción del Mayón en 1814 y el Traslado de Algunos Pueblos de la Iraya’, p.20, unpublished manuscript, Archives of the Manila Observatory Box 13, file 2/4. This manuscript is compiled by Miguel Selga and contains 24 first-hand accounts of the eruption and its aftermath, the original of which may no longer exist. Each account is given verbatim and in whole and preceded by a brief summary of its contents by Selga.
58 Ibid., p. 20.
seven years so as to allow them to properly establish a new town.\footnote{Ibid., pp. 25-28.} The inhabitants of Guinobatan petitioned for much the same favours, their parish priest, Fr Francisco Tubino, pointing out how in the space of 5½ hours “the work of countless years of sweat and toil by their ancestors had been lost”.\footnote{Ibid., p. 38.} In the event, the devastated towns of Budiao and Cagsawa were merged into a single settlement and removed to a new site at the village of Daraga much along the lines originally proposed in 1771. The extreme example of 1814 vividly demonstrates how the volcano exerted an influence over the actual location of settlements, attracting people to establish them in the first place, and then influencing their relocation to alternate sites according to the changing profile of its eruptions.

Not only did the volcano affect the spatial pattern of human settlement but its menacing presence influenced the minds of the people who lived in them. Volcanoes figure in the Bikol folk epic, the Ibálong, the extant verses of which clearly describe some cataclysmic eruption in pre-Hispanic times that caused extensive morphological changes to the surrounding landscape.\footnote{Mérito B. Espinas, \textit{A Critical Study of Ibálong the Bikol Folk Epic-Fragment}, reprinted from Unitas, University of Santo Tomas 41, 2 (1968), pp 30-31. See also Mérito B. Espinas, \textit{Ibalong: the Bikol Folk Epic Fragment: English and Bikol Translation, Views and Comments} (Legaspi City: M.C. Espinas, c1996).} Mayon is also the subject of myth in which a beautiful maiden, Magayón, and her lover are slain on her wedding day and she is subsequently transformed into the volcano. On days when the volcano’s summit is shrouded in clouds, old people say that the two are kissing.\footnote{Mérito B. Espinas, ‘The Legend of Dalagang Magayón’, \textit{Unitas}, 41, 2 (1968): np., reprinted in 1969.} With Christianity, however, natural hazards were typically depicted as forms of \textit{gaba} or divine punishment for one’s past actions or sins that fall on the innocent as well as the guilty.\footnote{Lilian C. Garcia, ‘Some Observations of the Gaba Phenomenon’, \textit{Philippine Quarterly of Culture and Society} 4 (1) (1976): 31-36.} Such is the recurring motif in most pre-twentieth century accounts of eruptions which are generally explained in such terms. The 1814 eruption, for example, is accounted for in terms of punishment for some unspecified wrongdoing. A circular from the Vicar General of Nueva Caceres distributed shortly after the eruption rationalized the event as a form of “Divine Justice, angry at our sins” and admonished priests and their congregations to be more prudent in the future.\footnote{Miguel Selga, ‘La Erupción del Mayón en 1914 y el Vicario General de Nueva Caceres’, Seismological Note No., unpublished manuscript, PHIVOLCS Library, MO57.} One of these parish priests, pondering on his own survival, asked “Who among us thought to remain alive in the face of such clear manifestations of divine Justice?”\footnote{Aragoneses, \textit{Suceso Espantoso}, p. 13.} Although these attitudes were beginning to be questioned in the late 19th century and to be replaced by more “scientific” explanations, the notion of a vengeful God persisted. A rare vernacular account, written in Bikol of the 1897 eruption, still refers to it as God’s “way of punishing people”.\footnote{Mariano, Perfecto, \textit{Bareta dapit can Volcan Mayong sa Albay can Junio de 1897} (Nueva Caceres: Imprenta “La Sagrada Familia”, 1897), pp. 16-17.} Nor have such attitudes completely died out in the contemporary Philippines.\footnote{Greg Bankoff, ‘In the Eye of the Storm: The Social Construction of the Forces of Nature and the Climatic and Seismic Construction of God in the Philippines’, \textit{Journal of Southeast Asian Studies} 35 (1) (2004): 91-111.}
In the final event, too, the volcano even interfered directly in human affairs, influencing the course of events. The 1897 eruption took place during a lull in the Philippine Revolution, while that of 1900 occurred during the Philippine American War. What little is known about the 1900 eruption comes from the report of US soldiers fighting in the Bikol region at the time. Quite apart from commenting on the “nerve-racking” experience the eruption had on the invading troops as the constant vibrations noisily rattled windows and doors, the volcanic dust seeped into every nook and cranny, contaminating food chests and affecting the reliability of watches and compasses. Even the troops’ rifles were rendered inoperative as the bolt mechanism jammed, making it impossible to reload. Captain Betts wrote how this difficulty only added “to our already many worries, for if our rifles could not be used we were at the mercy of the bolo men from whom we were expecting an attack in force at any time”. In the event, republican forces had been just as unsettled by the eruption and had moved away from the volcano into the interior as rapidly as possible. American soldiers also discovered that by cutting the toe out of a sock, slipping it over the barrel and tying each end around the bolt, there was ample room to empty and reload the magazine before the mechanism clogged again.

Society’s effect on volcanoes

More difficult to discern but no less influential is human society’s effect on the volcano. On first consideration, it may be thought that people exert no influence on volcanic activity, and, obviously, the proximity of human settlement has no bearing on the type or timing of eruptions. Mayon lies in a chain of ten, mostly dormant volcanic cones that form the Bikol Peninsula of south-eastern Luzon. Apart from Mayon, only Bulusan is known to be active and to have erupted 15 times since 1885. Most eruptions of Mayon are either Strombolian, small to medium in volume and consisting of the ejection of incandescent cinder, lapilli and lava bombs to altitudes of a few hundred metres, or Vulcanian, characterised by a dense cloud of ash-laden gas exploding from the crater and rising high above the peak, dispersing tephra and ash over a wide area of the surrounding countryside and usually ending with a flow of viscous lava. Human modification of the surrounding landscape, however, has had an influence on the course of eruptions, particularly in determining the direction of lava flows and lahars. Moreover, as human population and activities have intensified over the centuries so has this impact become more pronounced.

The number of people living in Albay province has risen steadily in recent years from approximately 246,000 people in 1887 to a total of 1,314,826 according to the 2015 Census. While this represents an annual growth rate of 1.32% over the last century or so, the

---

population has increased 2½ times since 1980.\textsuperscript{71} Earlier population densities are harder to estimate though the number of people living in the Bikol peninsula had risen from 146,100 in 1794 to 487,500 by 1887.\textsuperscript{72} It was a prosperous region. Fr. Aragoneses describes how intensive cultivation had reached even to the lower slopes of the volcano by 1814 which had been “converted into a wide and beautiful garden”. In the doomed town of Budiao, the town site closest to Mayon, the fertile fields yielded coconuts, cacao, abacá, all manner of fruit trees as well as root crops and vegetables.\textsuperscript{73} Enrique Abella y Casariego, the Spanish mining engineer who observed the 1882 eruption, noted how land was regularly cultivated to an altitude of 600m on the volcano’s flanks.\textsuperscript{74}

All this agricultural activity suggests that most of the forested areas had been cleared from around the base of the volcano by the beginning of the 19\textsuperscript{th} century. While nothing will prevent pyroclastic density currents and surges or check lahars and debris flows, barriers, whether constructed (concrete dikes and earthen embankments) or natural like forests will temporarily slow their descent and limit the area affected. Similarly, the removal of such barriers or deforestation has the opposite effect. Recent forest clearance on the southern flanks of Semeru Volcano in East Java by Madurese immigrants is blamed for aggravating the damage caused during eruptions or by heavy rainfall.\textsuperscript{75} An absence of trees, moreover, increases the run-off rate of rainwater and augments the number of flash floods that develop into devastating debris-flows as a result of the high sediment supply from the clear-felled slopes.\textsuperscript{76} The gradual deforestation of the land around Mount Mayon over the centuries but especially after 1800 has extended the area affected by all forms of run-off from the volcano and increased the number of people at risk.

On other occasions, there are recorded instances of human activity made with the express purpose of diverting lahars or debris-laden flash floods. Valuable commercial farmland was constantly at risk from mudflows especially during the traditional typhoon season between May and November. Faustino noted, however, how some plantation owners had devised ways and means to minimise the losses from such destructive flows by building dikes or dams to protect their properties. While such measures may have limited the damage to their own fields, such constructions only diverted the flow to other properties “so the destruction was no less”.\textsuperscript{77} After the 1984 eruption, too, the Japanese International Cooperation Agency (JICA) constructed a number of Sabo dams in downslope areas in an attempt to mitigate the destructive flow of lahars during heavy rains. These have been subsequently rendered

ineffective and abandoned (Photo 2) due to the constantly changing nature of the channels down the volcano’s flanks and the increased rate of sedimentation.\textsuperscript{78}

At other times, the effects of human ingenuity have had a more incidental but no less destructive impact in influencing the progress of eruptions. Under the American colonial administration, major infrastructural works were carried out both to promote trade and industry and facilitate the movement of troops and the Philippine Constabulary. In particular, all-weather roads and a railway were built to connect Manila with the provinces; the road and railway connecting Albay (now known as Legazpi) skirted around the base of the volcano, crossing each other at certain points. Not only did these excavations act as artificial “channels” directing the paths that the lahars and debris-flows took but they also inadvertently created barriers that constrained or steered such flows toward unintentional “natural” breaches at crossroads or other similar junctions. In the process, potentially lethal choke points were created where people, traffic and lahars might converge. At other times, lines of communication might be cut for months or even years by the boulders, sand, gravel and other volcanic debris washed down from the mountain: the road to Libog, for instance, damaged in the 1897 eruption was only finally reopened in 1912.\textsuperscript{79} Even today, as an interview with a senior civil engineer in the local office of the DPWH (Department of Public

Works and Highways) confirmed, little consideration is given to such matters in the planning or construction of the modern road network.  

Finally, the way humans have thought about the volcano has also changed, especially over the last century, and, in the process, had some bearing on the course of subsequent eruptions. There was a move to relocate the population immediately surrounding the volcano after the 1928 eruption, limiting the entry of future homesteaders and declaring Mayon a public park (Faustino 1929:41-42). In the event, the volcano was made a forest reserve in 1932, then declared a national park in 1938 by President Quezon before being proclaimed as Mayon Volcano Natural Park in 2000. Such designations, however, have not altogether prevented illegal settlers from farming its slopes. PHIVOLCS, too, as part of its disaster management strategy, has designated a six-kilometre radius Permanent Danger Zone (PDZ) around the volcano in which farmers and residents are advised to cease all activity in the event of an eruption. This zone is further extendable to eight kilometres in the high-risk area to the southeast of the volcano from which residents are evacuated in times of alert.  

As notions of conservation and risk have changed over the 20th century, prompting a reappraisal of who can live close to the volcano and what activities they can pursue, there has been a moderate rewilding of Mayon’s flanks, perhaps, with consequent effects upon more recent eruptions.

Conclusion

The history of the Philippines, as anywhere else, is largely shaped by the inter-relationship of the natural to the human, of the physical to the social. Susanna Hoffman and Anthony Oliver-Smith refer to this human-environmental interaction in terms of “mutuality” where the outcomes are determined by both factors acting upon each other. Both the culture of the society and the nature of the environment are the product of a long-term interaction over time. In order to understand the measure of this interaction, the risk so to speak, there is a need to, as Susan Stonich so aptly phrases it, “balance the cultural/social construction of nature with a meaningful consideration (and analysis) of the natural construction of the cultural and social”. Around Mayon, this mutuality is expressed in terms of a co-volcanic society where the mountain helps shape the culture of the human society around it, and the human society, in its turn, exerts an influence on the topography of the mountain and its natural processes. Disasters occur in this relationship “at the intersection of nature and culture and illustrate, often dramatically, the mutuality of each in the constitution of the other”.

80 Interview with DPWH civil engineer, Legazpi, 23 January 2018.
The hallmark of a co-volcanic society depends on whether eruptions have had a significant effect on the culture of the communities living around volcanoes and whether human activities have impacted upon their natural processes. As regards the former, it is not difficult to discern the effect of a volcano on local culture, whether as regards the actions taken that are more directly attributable to an eruption, or where disasters have acted more as a catalyst of change in the longer term. Archaeological evidence suggests that the key variable in this respect is not magnitude but frequency. Disasters which occur frequently over relatively long period of time can instigate adaptation and engender cultural change or, alternatively, they may retard any such developments. In this respect, disasters are perceived not so much as purely natural events but as also social ones that are explained or refuted according to how a threat is interpreted through a specific cultural and temporal lens.\textsuperscript{85} Unlike many other volcanoes in the Philippines that erupt irregularly at intervals of several centuries, Mayon is almost constantly in eruption. Faustino, for instance, estimated that there was an eruption about every four years, an average that still holds true depending on whether you include very small events.\textsuperscript{86} Here, then, are the three factors identified by Wenger and Weller as crucial to the emergence of a disaster subculture: Mayon erupts repetitively; the nature of these eruptions is mainly but not always heralded by a series of micro earthquakes, volcanic tremors, subterranean noises and an incandescent dome; and that the consequences of these eruptions inflict significant damage to human and material resources, most notably in 1814 and 1897. In the archipelago, only Taal Volcano proffers a similar profile.

However, a co-volcanic society is one where the hazard not only exerts an influence on human society but one also where the actions of that society affect the natural processes of the hazard. Here, of course, the evidence is more tentative and requires deeper research that may have to delve beyond simply the archival and documentary and require the collaboration of volcanologists, geographers and soil scientists amongst others. But even in the documentary record, there is sufficient evidence to suggest that human activities and the way people thought about the volcano have had some influence on, at least, how eruptions took place. Human activity and perceptions have modified the environment and the topography around the volcano and and thereby influenced in some measure the direction and extent of pyroclastic density currents, lahars and debris-flows.\textsuperscript{87} To some extent, at least, volcanic eruptions, or the manner in which they occur, are also social constructions.

Over the centuries, society and environment have adapted to one another to create a co-volcanic society around Mount Mayon. By drawing attention to the mutuality between society and environment, the concept of co-volcanic societies has important considerations for both historiography and contemporary DRR in the Philippines. As regards historiography, the notion of co-volcanic societies explores the ways in which environmental factors help shape the course of human history as well as highlighting the historical role of humans in

\textsuperscript{86} Faustino, ‘Mayon Volcano’, 34; Communication from local volcanologist, Salvacion, 15 November 2018.

modifying environmental processes. The volcano must loom large in any history of the region that is shaped not just by human activity but also by natural processes. Historically, the population of Albay has been governed by the dynamics of diametrically opposing forces: the menace of the volcano that drives people away from the hinterland towards the coast on the one hand, and the threat of Moro raiders whose depredations forced people to abandon the coast for the safety of settlements further inland on the other hand. How exactly these forces have shaped settlement patterns in Albay is beyond the scope of this article but certainly worthy of further consideration. The concept of co-volcanic societies reveals how risk is not simply a product of human social structures (i.e. the power relations within society) but also the outcome of “natural structures” (i.e. the balance of forces within the physical world).

Also, by drawing attention to the importance of culture in determining people’s behaviour in the face of danger, the concept of co-volcanic societies has important application for contemporary DRR in the Philippines. In the first place, it reveals the compound nature of risk, that it is both the product of the interaction between the physical world and human activity. Second, it highlights the importance of the local, the specific, the situational and the contextual, emphasising, in particular, the importance of historical considerations to any understanding of vulnerability and so DRR. Third, it questions the validity of terminological classifications: as Mayon quite clearly illustrates “volcanoes ain’t volcanoes”; that is some volcanoes are very active and the risk posed by them very much depends on how frequently they erupt. Classifying volcanoes as either active or dormant or by their structure and composition (strato, dome, shield and cinder) pays insufficient attention to the human dimension. And, finally, thinking about societies as co-volcanic highlights how vulnerability is the product of culture. Culture or the way people perceive the world around them and act according to traditional patterns of behaviour over time should be a significant factor in determining the success of any measures taken to reduce risk. As Faustino observed shortly after the 1928 eruption of Mayon:

“The trees and plants damaged in July have recovered and once more the plains and slopes of Mayon are covered with green vegetation. People have returned to their homes, and the disturbance which caused no little commotion and mobilised all the government forces and the Philippine Chapter of the Red Cross has settled down – to wait for the next eruption [emphasis added]”.  

As the history of the communities around Mount Mayon shows, societies that live under a volcano form part of a single interdependent system, each influencing the other, that together co-evolve over time.
